ABSTRACT

There is provided a mobile phone that detects bio-information on the user and makes information communications reflecting the detected bio-information. mobile phone (1) includes sensors (18) that detect bio-information data. bio-information data detected by the sensors (18) are sent to a sensor data analyzer (19) in which psychology corresponding to the detected bio-information data is analyzed based on bio-information data stored in a psychology memory (20) and The sensor data analyzer (19) extracts characteristic signal psychology of the user. patterns from the bio-information data detected by the sensors (18) and analyzes psychology corresponding to th extracted signal patterns. The psychology includes, for example, "pleased and delightful", "discouraged", "excited", etc. and these states of mind are stored in association with bio-information data in the psychology memory When the bio-information data are detected by the sensors (18), psychology most matching the bio-information data is selectively read out of the psychology memory (20).
